TEMPERATURE AND SALINITY OBSERVATIONS
AT SURFACE AND NEAR BOTTOM OVER THE EASTERN BERING SEA SHELF,
AVERAGED BY $1^{\circ} \times 1/2^{\circ}$ SQUARES

INTRODUCTION

Water temperature affects growth, migrations, and survival of all biota in the sea. The seasonal and annual variations in water temperature are quite pronounced in high latitudes such as the Bering Sea where also pronounced anomalies can occur over the extensive, shallow eastern Bering Sea shelf. These anomalies must be taken into account in fisheries research, predictions, and in holistic ecosystem modeling.

To detect environmental anomalies, we must first know mean conditions. This report is an attempt to summarize the available observations of temperature and salinity from the eastern Bering Sea on a monthly time and $1^{\circ} \times 1/2^{\circ}$ space scale. The general ocean conditions and features which appear in these mean data charts presented here are discussed by Ingraham (1981). Earlier data summaries and atlases for the Bering Sea were presented by Laviolette and Seim (1969), Ingraham (1973), and Robinson and Bauer (1976).

DATA SUMMARY

The computer file for the eastern Bering Sea contains about 9,000 Bathythermograph (mechanical and expendable) and 10,000 Nansen cast salinity, temperature, and depth data stations from 1932 to June 1979. NODC (National Oceanographic Data Center) data files were the primary source of the salinity and temperature data before 1975. More recent data were obtained by NWAFC (Northwest and Alaska Fisheries Center), IPHC (International Pacific Halibut Commission), OCSEAP (Outer Continental Shelf Environmental Assessment Program) and PROBES (Processes and Resources of the Eastern Bering Sea) groups, and some data were obtained from Russian and Japanese publications. The total of 19,126 stations from the eastern Bering Sea averages only about 400 stations per year or 33 per month over a large eastern Bering Sea area of about $1.5 \times 10^6 \text{ km}^2$. There were no data from 1942-46 or from 1950 or 1952. Also, no data were taken during any December, and November and January data totaled less than 50 stations each. The best data coverage was from 1975-78 with a maximum of about 2,000 stations in 1976.

The data were tested by various quality control criteria which reduced the number of acceptable data points. The rejection criteria for the various quality controls which were imposed while sorting the data, were:

1. Outside of latitude range, 54° - 68° N;
2. Outside of longitude range, 175° E- 157.2° W;
3. Station depth greater than twice chart depth (position error implied on shelf);
4. Temperature values identically zero (missing data) or less than -2.0°C ;
5. Salinity values less than $10^{\circ}/\text{oo}$; and
6. Bottom values more than 15 m or greater than 20% of water depth from the bottom.

Accepted values were sorted by location into $1/2^{\circ}$ (lat.) and 1° (long.) squares. Simple monthly arithmetic means were computed for each square and written by Calcomp Plotter in the center of each square on a Mercator map (Figures 1 to 43). The smaller number below each mean value is the number of observations used to compute each mean. The distribution of the number of final data values in time (by month and by year) for each parameter are shown in Tables 1-4, respectively. This report contains charts of long-term monthly mean sea surface temperature (Figures 1-11), near bottom temperature (Figures 12-22), surface salinity (Figures 23-33), and near bottom salinity (Figures 34-44). Because of the absence of data, no December monthly means are presented.

Caution is advised that there are several limitations to the presentations of mean conditions in this report. First, the amount of data are not sufficient for summaries by $1^{\circ} \times 1/2^{\circ}$ quadrangles (nor even $2 \times 2^{\circ}$). Thus, there are numerous spatial data gaps in each month. Data from October to March were very limited. Secondly, the data from warm and cold years are not equally distributed; in some instances the values represent conditions in warm or cold years. The paucity of data can create isolated anomalous values and tongue-like protrusions that may merely reflect a preponderance of data from a single anomalous year rather than a significant mean environmental feature. Nevertheless, the data reflect a high degree of continuity of conditions throughout the area that cannot be obtained in any other manner.
